1 Statistical Learning Theory

- Let $D_n$ be a training set of examples $z_i$ drawn independently from unknown $p(z)$
- We need a set of functions $\mathcal{F}$. Example: linear functions $f(x) = a \cdot x + b$
- We need a loss function $L(z, f)$. Example: $L((x, y), f) = (f(x) - y)^2$
- Expected Risk: $R(f) = \mathbb{E}_Z[L(z, f)] = \int_Z L(z, f)p(z)dz = \text{generalization error}$
- Empirical Risk: $\hat{R}(f, D_n) = \frac{1}{n} \sum_{i=1}^{n} L(z_i, f)$
- Empirical Risk Minimization: $f^*(D_n) = \arg\min_{f \in \mathcal{F}} \hat{R}(f, D_n)$
- Training error: $\hat{R}(f^*(D_n), D_n)$
- Difference between Expected Risk and Empirical Risk bounded but depends on capacity
- Curves show that there is an optimal capacity:

- Methodology:
  - empirical risk minimization on a training set $D^{tr}$  
    $$f^*(D^{tr}) = \arg\min_{f \in \mathcal{F}} \hat{R}(f, D^{tr})$$  
  - model selection on a validation set $D^{va}$  
    $$\theta^*_m = \arg\min_{\theta_m} R(f^*_\theta(D^{tr}), D^{va})$$  
  - estimation of the expected risk on a separate test set $D^{te}$  
    $$R(f^*_\theta(D^{tr} \cup D^{va}), D^{te})$$  
  - if data is small, consider cross-validation
